BTC perpetuals, settled in MUSD.

Long or short BTC/USD with 1-100x leverage. A loss-funded house replaces external LP deposits.

Trade with MUSD

Margin, payouts and fee revenue use Mezo's Bitcoin-backed stablecoin.

Launch without LPs

The house grows from realised losses. Profits can wait in a FIFO queue.

Receive MPAPER

Realised losses mint a staking token. MUSD rewards depend on future revenue.

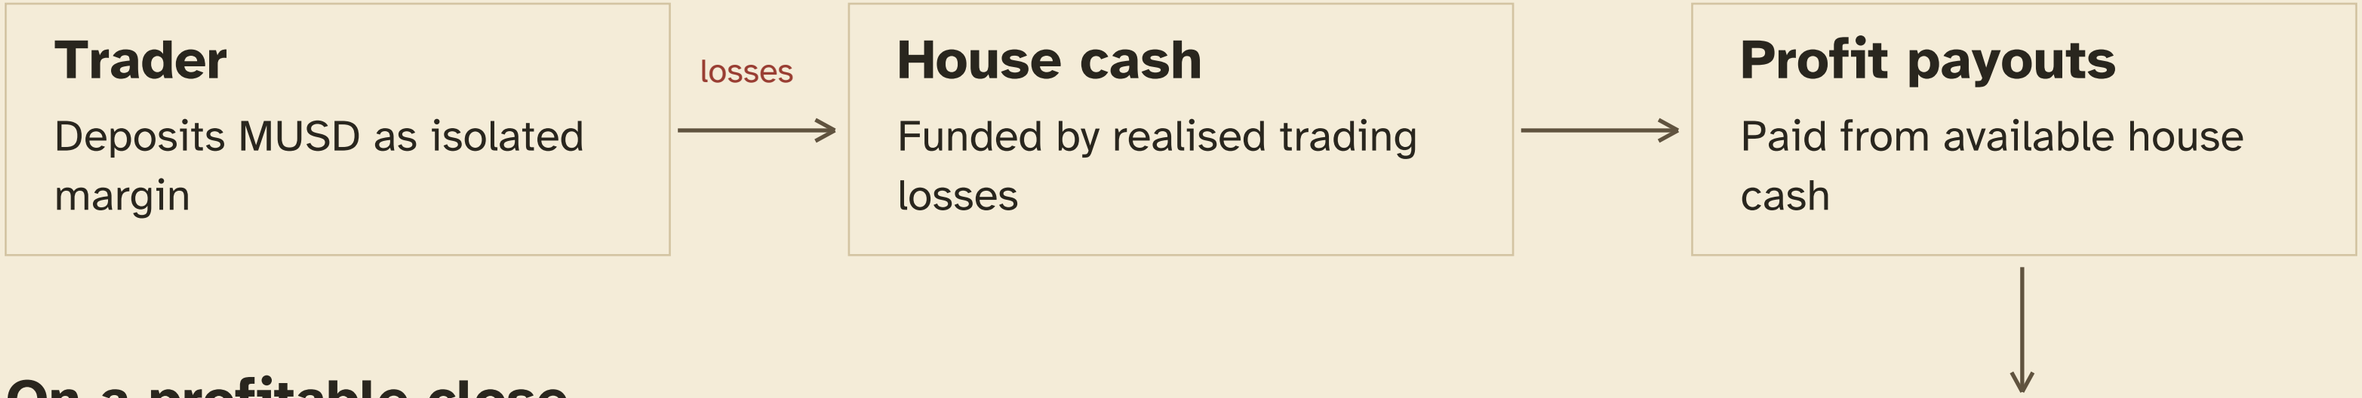

Try the app

Public code

Track 1: DeFi

No LP deposits. A visible payout trade-off.

The house never spends open-position margin to pay another trader's profit.

On a profitable close

Posted margin is returned immediately. Net profit is subject to the impact haircut and fee, then house cash and queue priority.

MPAPER staking Variable MUSD fee revenue and house excess. It does not reimburse trading losses.

See the bust line before you request a trade.

Public testnet capture, 26 Oct 2026. Empty account shown. This screenshot is not an executed trade.

Trade

Long / short. MUSD margin. A keeper fills at a later published price.

House

House cash, queued profit and every open position.

MPAPER

Stake and claim available MUSD revenue.

What is active, and what still needs trust.

Active on Mezo testnet

MUSD margin, settlement and staking

Mezo Passport wallet interface

Team-signed median spot price

Two-step opens and closes

Keeper on Cloudflare Workers

Explicit limits

Unaudited contracts and one team-run keeper

A team key signs the active price feed

Skip +/-1% check applies while Skip is fresh

Stale / invalid Skip data disables that bound

Owner can change oracle and risk settings

Pyth Deployed and fork-tested with signed update data. Not the active oracle in this submission.

Demo prices The separate crash demo uses a mock oracle. It is not evidence of a live market crash.

Three kinds of proof, kept separate.

Live feed / current v2 market

A deployer-owned 100x long was liquidated on 26 Oct 2026 using the regular signed-price keeper. Testnet, not independent adoption.

Read the live-liquidation transaction

Historical queue repayment / v1

A winning close queued profit. A later losing close repaid it. This is a legacy market, separate from the current v2 UI.

Read the deployment evidence

Controlled crash / separate demo

A mock-price testnet market and local fork demonstrate queue repayment, liquidation, and staking without waiting for BTC to move.

Read the recorded local-fork run

Review it without a wallet. Trade with test assets.

1. Inspect Open the app. Check oracle age, house cash, queue and open interest. House and MPAPER tabs are read-only until you sign.

2. Fund and request Get faucet BTC, then swap or borrow MUSD on Mezo testnet. Connect with Passport. Minimum margin is 10 MUSD. Wait for a keeper fill.

3. Close and review Close a position, inspect payout conditions, then inspect or stake MPAPER after a realised loss. The judge guide links each proof.

Next Wave 2: first-trade guidance, queue-risk scenarios and validation of the Pyth migration. After that: external review, admin controls and a capped mainnet decision.
